

## E: Tax burden refresher

### Tax burden:

Portion of a tax borne by a given agent: buyer or seller

### Notation and accounting:

$P_i^d$  Price paid by buyers in equilibrium  $i$

$P_i^s$  Price received by sellers in equilibrium  $i$

$Q_i^m$  Market quantity traded in equilibrium  $i$

Relationship between prices:  $P_i^d = P_i^s + t$

### Example using hypothetical results:

#### Equilibrium 1: no tax

Suppose:

$$P_1^d = 80$$

$$P_1^s = 80$$

$$Q_1^m = 1000$$

## Equilibrium 2: \$10 unit tax

Suppose:

$$P_2^D = 84$$

$$P_2^S = 74$$

$$Q_2^M = 900$$

## Analysis:

Revenue collected:

$$T * Q_2^M = \$10 * 900 = \$9000$$

Impact of tax on prices:

$$\Delta P^D = 84 - 80 = 4 \quad \text{Buyers worse off by \$4}$$

$$\Delta P^S = 74 - 80 = -6 \quad \text{Sellers worse off by \$6}$$

$$\text{Relation between impacts and tax: } \Delta P^D - \Delta P^S = T$$

Revenue paid by each group:

Group	Revenue	Share of revenue	Percent
Buyers:	$\$4 \times 900 = \$3,600$	$\$3600/\$9000 = 0.4$	40%
Sellers:	$\$6 \times 900 = \$5,400$	$\$5400/\$9000 = 0.6$	60%

Tax burdens via price changes alone:

Group	Share of T	Percent
Buyers:	$\$4/\$10 = 0.4$	40%
Sellers:	$\$6/\$10 = 0.6$	60%
