## Deducing Preferences from Behavior

## Fundamental strategy

1. Collect data on bundles purchased
2. Find demand equations that match

Result:

- Allows predictions of response to policies ( $\Delta \mathrm{Q}$, etc)
- Allows measurement of welfare impacts ( $\Delta S S$, etc)

## Example:

Observe a household during two periods, months 1 and 2:

| Observation | $M$ | $P_{x}$ | $P_{y}$ | $Q_{x}$ | $Q_{y}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 100 | 1 | 2 | 20 | 40 |
| 2 | 120 | 2 | 2 | 12 | 48 |

Blue: Economic conditions
Yellow: Choice

Look for demand equations that are consistent with the data
Fundamental process:

1. Guess a general demand equation
2. Use first observation to calculate unknown parameters
3. Test prediction on second observation
4. Reject guess and try again if the prediction is wrong

## Try PC

General demand for $X$ :

$$
Q_{x}=\frac{\beta M}{\beta P_{x}+P_{y}}
$$

Inserting data for observation 1:

$$
\begin{aligned}
M & =100, P_{x}=1, P_{y}=2, Q_{x}=20 \\
20 & =\frac{\beta * 100}{\beta * 1+2}
\end{aligned}
$$

Solving for $\beta$ :

$$
\begin{aligned}
& 20(\beta+2)=100 \beta \\
& 20 \beta+40=100 \beta \\
& 40=80 \beta \\
& \beta=0.5
\end{aligned}
$$

Conclusion: PC demand that fits observation 1

$$
Q_{x}=\frac{0.5 M}{0.5 P_{x}+P_{y}}
$$

Predicting $Q_{x}$ for observation 2

$$
\begin{aligned}
& M=120, P_{x}=2, P_{y}=2 \\
& Q_{x}=\frac{0.5 * 120}{0.5 * 2+2}=\frac{60}{3}=20
\end{aligned}
$$

Compare with actual for observation 2 :

Observed $Q_{x}=12$

Conclusion: reject PC Behavior is not consistent with PC preferences

Important note

Must compare one demand for two observations

- First observation to calculate the parameter
- Second observation to test the prediction

Not equivalent to use two demands and one observation

## Try CD

General demand for X :

$$
Q_{x}=\frac{a M}{P_{x}}
$$

Inserting data for observation 1:

$$
\begin{aligned}
& \mathrm{M}=100, P_{x}=1, P_{y}=2, Q_{x}=20 \\
& 20=\frac{a * 100}{1}
\end{aligned}
$$

Solving for $a$

$$
a=\frac{20}{100}=0.2
$$

Conclusion: CD demand that fits observation 1:

$$
Q_{x}=\frac{0.2 M}{P_{x}}
$$

Predicting $Q_{x}$ for observation 2

$$
\begin{aligned}
& M=120, P_{x}=2, P_{y}=2 \\
& Q_{x}=\frac{0.2 * 120}{2}=\frac{24}{2}=12
\end{aligned}
$$

Compare with actual for observation 2:

$$
\text { Observed } Q_{x}=12
$$

Conclusion: can't reject CD
Behavior is consistent with CD preferences

## General approach

- Use econometrics to fit demand equations
- Conceptually, follows steps above

Quick tests for some preferences

If preferences are PC:

$$
\frac{Q_{x}}{Q_{y}}=\beta
$$

Can test by checking ratio for two observations:

| Observation | $Q_{x}$ | $Q_{y}$ | $\beta$ |
| :--- | :--- | :--- | :--- |
| 1 | 20 | 40 | $20 / 40=0.5$ |
| 2 | 12 | 48 | $12 / 48=0.25$ |

Differs: reject PC

CD

If preferences are CD:

$$
\frac{P_{x} Q_{x}}{M}=a
$$

Checking share for two observations:

| Observation $M$ | $P_{x}$ | $Q_{x}$ | $a$ |  |
| :--- | :--- | :--- | :--- | :--- |
| 1 | 100 | 1 | 20 | $1^{*} 20 / 100=0.2$ |
| 2 | 120 | 2 | 12 | $2 * 12 / 120=0.2$ |

Same: CD is consistent; can't reject

## Daily exercise
